Product Design Brief

1. Project Overview

This is a workflow-based AI application case study.

It explores how AI can identify, structure, review, route, and track multi-source business signals across sales, CRM, customer support, quality, meetings, and regional feedback.

It is not:

- a meeting summary tool;
- an automatic task dispatch system;
- a fully autonomous agent;
- a production deployment claim.

2. Core Problem

Many enterprises already collect business feedback across multiple systems, but the signals are scattered, mixed, and difficult to turn into accountable action.

Five breakpoints:

- Scattered signals;
- Mixed types;
- Unclear ownership;
- Hard-to-track status;
- Delayed review and learning.

3. Running Scenario

The running scenario uses a recurring signal around rear-seat comfort, family users, and sales conversion risk.

A single feedback item may look like a local sales objection. But once combined with CRM records, customer support feedback, regional meeting notes, and market observations, it may reveal a broader product experience issue and a sales conversion risk.

In this scenario, AI does not make the final business decision. It helps aggregate similar feedback, extract evidence, draft a reviewable business card, suggest likely responsible teams, and make the issue visible for human confirmation.

4. Before and After AI

Before AI:

Multi-source signals -> manual collection -> manual classification -> meetings -> manual routing -> chat / spreadsheet tracking -> delayed review.

After AI:

Multi-source signals -> AI identification, classification, and clustering -> evidence extraction -> requirement / issue / risk card draft -> human confirmation -> routing to responsible teams -> status tracking -> operational insight and rule updates.

5. AI Intervention Points

AI acts as:

- signal detector;
- classifier and clustering assistant;
- evidence extractor;
- card draft generator;
- routing suggestion assistant;
- risk reminder;
- insight assistant.

Humans remain responsible for:

- confirming classification;
- judging priority;
- confirming ownership;
- deciding whether to enter a formal workflow;
- closing tasks;
- deciding what becomes a rule or insight.

6. Lightweight AI Business Signal Layer

This product does not replace CRM, customer support, quality, or project management systems.

A lightweight AI business signal layer sits between existing systems. It helps aggregate signals, extract evidence, support human review, synchronize status, and update routing or review rules.

The layer is intentionally lightweight. Its role is to connect signals and workflows, not to become a heavy enterprise platform.

7. Core Product Responsibility Unit

The core chain is:

Signal Pool -> AI Identification -> Requirement / Issue / Risk Card -> Human Confirmation -> Routing and Status Tracking -> Operational Insight and Rule Learning.

Step	Input	AI role	Human role	Output
Signal Pool	Sales, CRM, support, quality, meetings, and regional feedback	Normalize and prepare multi-source signals	Confirm source scope and business relevance	A unified signal pool with source evidence
AI Identification	Raw or semi-structured signals	Classify, cluster, tag, and extract evidence	Review whether the signal type is correct	Structured signals with evidence snippets
Requirement / Issue / Risk Card	Identified business theme	Draft a card with type, impact, evidence, and suggested owner	Confirm priority, ownership, and whether it should enter workflow	A reviewable business object
Human Confirmation	Draft card and evidence	Surface confidence, similar issues, and routing suggestions	Decide what is valid, what is noise, and what should move forward	Confirmed card
Routing and Status Tracking	Confirmed card	Suggest responsible teams and flag delay or blockers	Own the task, update status, and close with reasons	Trackable organizational action
Operational Insight and Rule Learning	Closed-loop data and review records	Summarize trends and repeated issues	Decide which insights become rules, playbooks, or management inputs	Updated rules and operational insight

8. Key Interfaces

The intended interface set includes:

- Overview Dashboard: shows signal health, pending cards, open risks, and response status.
- Multi-source Signal Pool: collects business feedback before it is lost across channels.
- AI Identification Result: presents category, confidence, evidence snippets, similar issues, and human correction entry.
- Requirement / Issue / Risk Card: turns scattered feedback into an object that can be reviewed, routed, and tracked.
- Routing Board: shows owner, status, blockers, delayed items, and closure records.
- Operational Insight / Review Page: turns recurring signals, closure data, and team response into management insight.

These are product interface designs and prototype planning artifacts, not claims of a deployed enterprise system.

9. Product Evolution

V1 | Signal Structuring

Make business signals visible.

Core capabilities:

- multi-source input;
- AI classification;
- evidence extraction;
- duplicate issue detection;
- draft card generation;
- human confirmation.

V2 | Routing Closure

Turn signals into accountable action.

Core capabilities:

- card typing;
- owner suggestion;
- routing board;
- status tracking;
- delay / blocker alerts;
- closure reason logging.

V3 | Operational Insight

Turn closed-loop data into management insight and rules.

Core capabilities:

- trend analysis;
- review reports;
- team response efficiency;
- high-frequency issue learning;
- sales / product / quality rule updates.

10. Validation and Boundary

This is a scenario-based product design case study, not a claim of production deployment.

Potential validation metrics:

- classification accuracy;
- human correction rate;
- card confirmation rate;
- owner confirmation rate;
- closure rate;
- average closure cycle;
- team response efficiency;
- rule update quality.

Boundary:

- no claim of real automaker or manufacturing deployment;
- no claim of actual sales uplift, complaint reduction, or cost saving;
- not a fully automated dispatch system;
- not a replacement for CRM, support, quality, or project management systems;
- not an autonomous decision-maker.

11. Product Value

This project demonstrates how AI can move from “planning” to workflow execution support by turning scattered business signals into confirmed, routed, tracked, and reviewable organizational action.
